

Total pages read is cumulative as of the selected day · both day bars share one scale (larger value fills)

Stepping back rewinds the total; the list scales every row against one global max so days compare

SPEC Annotation only. **Total pages read** is cumulative pages actually read ÷ book length **as of the selected day** — sum every log up to and including that date, so stepping back rewinds it (3 Sep shows 124; +12 on 4 Sep and +12 on 5 Sep bring today to 148). Show today's figure as a subtitle when a past day is selected. **The two day bars** are scoped to the selected date and share one scale: the higher of that day's two values fills 100% (5 Sep → could've 59 fills, read 12 = 20%; 3 Sep → read 22 fills, could've 20 = 91%), so the pair is directly comparable. "pages read today" keeps the label even on a past day, matching the day shown in the stepper. **The all-days list uses a different rule on purpose:** one global max across every listed day (here 64) so rows compare against each other, not just within a row. **Stepper** walks one logged day at a time; the > arrow disables on today, and unlogged days appear in the list but are skipped by the arrows. Deep-link a day with `?day=`.
